MAXIM

400ksps, +5V, 8-/4-Channel, 10-Bit ADCs with +2.5V Reference and Parallel Interface

MAX1090/MAX1092

General Description

The MAX1090/MAX1092 low-power, 10-bit analog-to-digital converters (ADCs) feature a successive-approximation ADC, automatic power-down, fast wake-up (2µs), an on-chip clock, +2.5V internal reference, and a high-speed, byte-wide parallel interface. The devices operate with a single +5V analog supply and feature a V_{LOGIC} pin that allows them to interface directly with a +2.7V to +5.5V digital supply.

Power consumption is only 10mW (V_{DD} = V_{LOGIC}) at a 400ksps max sampling rate. Two software-selectable power-down modes enable the MAX1090/MAX1092 to be shut down between conversions; accessing the parallel interface returns them to normal operation. Powering down between conversions can cut supply current to under 10µA at reduced sampling rates.

Both devices offer software-configurable analog inputs for unipolar/bipolar and single-ended/pseudo-differential operation. In single-ended mode, the MAX1090 has eight input channels and the MAX1092 has four input channels (four and two input channels, respectively, when in pseudo-differential mode).

Excellent dynamic performance and low power, combined with ease of use and small package size, make these converters ideal for battery-powered and data-acquisition applications or for other circuits with demanding power consumption and space requirements.

The MAX1090/MAX1092 tri-states $\overline{INT}$ when $\overline{CS}$ goes high. Refer to the MAX1060/MAX1064 if tri-stating $\overline{INT}$ is not desired.

The MAX1090 is available in a 28-pin QSOP package, while the MAX1092 comes in a 24-pin QSOP. For pin-compatible +3V, 10-bit versions, refer to the MAX1091/MAX1093 data sheet.

Applications

|	
Industrial Control Systems	Data Logging
Energy Management	Patient Monitoring
Data-Acquisition Systems	Touchscreens

Ordering Information

PART	TEMP RANGE	PIN-PACKAGE	INL (LSB)
MAX1090ACEI	0°C to +70°C	28 QSOP	±0.5
MAX1090BCEI	0°C to +70°C	28 QSOP	±1
MAX1090AEEI	-40°C to +85°C	28 QSOP	±0.5
MAX1090BEEI	-40°C to +85°C	28 QSOP	±1

Ordering Information continued at end of data sheet.

Features

♦ **10-Bit Resolution, ±0.5 LSB Linearity**

♦ **+5V Single-Supply Operation**

♦ **User-Adjustable Logic Level (+2.7V to +5.5V)**

♦ **Internal +2.5V Reference**

♦ **Software-Configurable Analog Input Multiplexer**
   8-Channel Single-Ended/
   4-Channel Pseudo-Differential (MAX1090)

   4-Channel Single-Ended/
   2-Channel Pseudo-Differential (MAX1092)

♦ **Software-Configurable Unipolar/Bipolar Analog Inputs**

♦ **Low Current: 2.5mA (400ksps)**
                1.0mA (100ksps)
                400µA (10ksps)
                2µA (Shutdown)

♦ **Internal 6MHz Full-Power Bandwidth Track/Hold**

♦ **Byte-Wide Parallel (8 + 2) Interface**

♦ **Small Footprint: 28-Pin QSOP (MAX1090)**
                     24-Pin QSOP (MAX1092)

Pin Description

PIN		NAME	FUNCTION
MAX1090	MAX1092		
1	1	HBEN	High Byte Enable. Used to multiplex the 10-bit conversion result. 1: 2 MSBs are multiplexed on the data bus. 0: 8 LSBs are available on the data bus.
2	2	D7	Three-State Digital I/O Line (D7)
3	3	D6	Three-State Digital I/O Line (D6)
4	4	D5	Three-State Digital I/O Line (D5)
5	5	D4	Three-State Digital I/O Line (D4)
6	6	D3	Three-State Digital I/O Line (D3)
7	7	D2	Three-State Digital I/O Line (D2)
8	8	D1/D9	Three-State Digital I/O Line (D1, HBEN = 0; D9, HBEN = 1)
9	9	D0/D8	Three-State Digital I/O Line (D0, HBEN = 0; D8, HBEN = 1)
10	10	$\overline{INT}$	$\overline{INT}$ goes low when the conversion is complete and the output data is ready.
11	11	$\overline{RD}$	Active-Low Read Select. If $\overline{CS}$ is low, a falling edge on $\overline{RD}$ enables the read operation on the data bus.
12	12	$\overline{WR}$	Active-Low Write Select. When $\overline{CS}$ is low in internal acquisition mode, a rising edge on $\overline{WR}$ latches in configuration data and starts an acquisition plus a conversion cycle. When $\overline{CS}$ is low in external acquisition mode, the first rising edge on $\overline{WR}$ ends acquisition and starts a conversion.
13	13	CLK	Clock Input. In external clock mode, drive CLK with a TTL/CMOS-compatible clock. In internal clock mode, connect this pin to either V_{DD} or GND.
14	14	$\overline{CS}$	Active-Low Chip Select. When $\overline{CS}$ is high, digital outputs ($\overline{INT}$, D7–D0) are high impedance.
15	—	CH7	Analog Input Channel 7
16	—	CH6	Analog Input Channel 6
17	—	CH5	Analog Input Channel 5
18	—	CH4	Analog Input Channel 4
19	15	CH3	Analog Input Channel 3
20	16	CH2	Analog Input Channel 2
21	17	CH1	Analog Input Channel 1
22	18	CH0	Analog Input Channel 0
23	19	COM	Ground Reference for Analog Inputs. Sets zero-code voltage in single-ended mode and must be stable to ±0.5 LSB during conversion.
24	20	GND	Analog and Digital Ground
25	21	REFADJ	Bandgap Reference Output/Bandgap Reference Buffer Input. Bypass to GND with a 0.01µF capacitor. When using an external reference, connect REFADJ to V_{DD} to disable the internal bandgap reference.
26	22	REF	Bandgap Reference Buffer Output/External Reference Input. Add a 4.7µF capacitor to GND when using the internal reference.
27	23	V_{DD}	Analog +5V Power Supply. Bypass with a 0.1µF capacitor to GND.
28	24	V_{LOGIC}	Digital Power Supply. V_{LOGIC} powers the digital outputs of the data converter and can range from +2.7V to V_{DD} + 300mV.

**МАХИМ**

MAX1090/MAX1092

Figure 2. Simplified Functional Diagram of 8-/4-Channel MAX1090/MAX1092

Detailed Description

Converter Operation

The MAX1090/MAX1092 ADCs use a successive-approximation (SAR) conversion technique and an input track-and-hold (T/H) stage to convert an analog input signal to a 10-bit digital output. Their parallel (8 + 2) output format provides an easy interface to standard microprocessors (µPs). Figure 2 shows the simplified internal architecture of the MAX1090/MAX1092.

Single-Ended and Pseudo-Differential Operation

The sampling architecture of the ADC's analog comparator is illustrated in the equivalent input circuits in Figures 3a and 3b. In single-ended mode, IN+ is internally switched to channels CH0–CH7 for the MAX1090 (Figure 3a) and to CH0–CH3 for the MAX1092 (Figure 3b), while IN- is switched to COM (Table 3). In differential mode, IN+ and IN- are selected from analog input pairs (Table 4).

In differential mode, IN- and IN+ are internally switched to either of the analog inputs. This configuration is pseudo-differential in that only the signal at IN+ is sampled. The return side (IN-) must remain stable within ±0.5 LSB (±0.1 LSB for best performance) with respect to GND during a conversion. To accomplish this, connect a 0.1µF capacitor from IN- (the selected input) to GND.

During the acquisition interval, the channel selected as the positive input (IN+) charges capacitor C_{HOLD}. At the end of the acquisition interval, the T/H switch opens, retaining the charge on C_{HOLD} as a sample of the signal at IN+.

The conversion interval begins with the input multiplexer switching C_{HOLD} from the positive input (IN+) to the negative input (IN-). This unbalances node ZERO at the comparator's positive input. The capacitive digital-to-analog converter (DAC) adjusts during the remainder of the conversion cycle to restore node ZERO to 0V within the limits of 10-bit resolution. This action is equivalent to transferring a 12pF [(V_{IN+}) - (V_{IN-})] charge from C_{HOLD} to the binary-weighted capacitive DAC, which in turn forms a digital representation of the analog input signal.
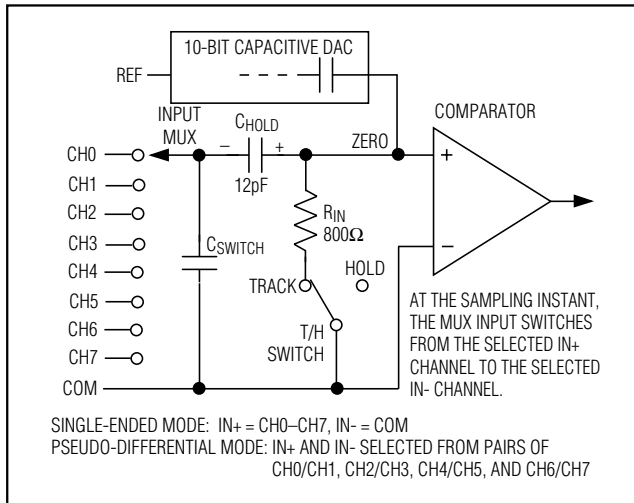

Figure 3a. MAX1090 Simplified Input Structure

Figure 3b. MAX1092 Simplified Input Structure

Analog Input Protection

Internal protection diodes, which clamp the analog input to V_{DD} and GND, allow each input channel to swing within (GND - 300mV) to (V_{DD} + 300mV) without damage. However, for accurate conversions near full scale, neither input should exceed (V_{DD} + 50mV) or be less than (GND - 50mV).

If an off-channel analog input voltage exceeds the supplies by more than 50mV, limit the forward-bias input current to 4mA.

Track/Hold

The MAX1090/MAX1092 T/H stage enters its tracking mode on the rising edge of $\overline{WR}$. In external acquisition mode, the part enters its hold mode on the next rising edge of $\overline{WR}$. In internal acquisition mode, the part enters its hold mode on the fourth falling edge of the clock after writing the control byte. Note that, in internal clock mode, this is approximately 1µs after writing the control byte.

In single-ended operation, IN- is connected to COM and the converter samples the positive (+) input. In pseudo-differential operation, IN- connects to the negative input (-) and the difference of |(IN+) - (IN-)| is sampled. At the beginning of the next conversion, the positive input connects back to IN+ and C_{HOLD} charges to the input signal.

The time required for the T/H stage to acquire an input signal depends on how quickly its input capacitance is charged. If the input signal's source impedance is high, the acquisition time lengthens and more time must be allowed between conversions. The acquisition time, t_{ACQ}, is the maximum time the device takes to acquire the signal and is also the minimum time required for the signal to be acquired. Calculate this with the following equation:

$$t_{ACQ} = 7\,(R_S + R_{IN})\,C_{IN}$$

where R_S is the source impedance of the input signal, R_{IN} (800Ω) is the input resistance, and C_{IN} (12pF) is the input capacitance of the ADC. Source impedances below 3kΩ have no significant impact on the MAX1090/MAX1092's AC performance.

Higher source impedances can be used if a 0.01µF capacitor is connected to the individual analog inputs. Along with the input impedance, this capacitor forms an RC filter, limiting the ADC's signal bandwidth.

Input Bandwidth

The MAX1090/MAX1092 T/H stage offers a 350kHz full-linear and a 6MHz full-power bandwidth. These features make it possible to digitize high-speed transients and measure periodic signals with bandwidths exceeding the ADC's sampling rate by using undersampling techniques. To avoid aliasing high-frequency signals into the frequency band of interest, anti-alias filtering is recommended.

Starting a Conversion

Initiate a conversion by writing a control byte that selects the multiplexer channel and configures the MAX1090/MAX1092 for either unipolar or bipolar operation. A write pulse ($\overline{WR}$ + $\overline{CS}$) can either start an acquisition interval or

initiate a combined acquisition plus conversion. The sampling interval occurs at the end of the acquisition interval. The ACQMOD (acquisition mode) bit in the input control byte (Table 1) offers two options for acquiring the signal: an internal and an external acquisition. The conversion period lasts for 13 clock cycles in either the internal or external clock or acquisition mode. Writing a new control byte during a conversion cycle aborts the conversion and starts a new acquisition interval.

Internal Acquisition

Select internal acquisition by writing the control byte with the ACQMOD bit cleared (ACQMOD = 0). This causes the write pulse to initiate an acquisition interval whose duration is internally timed. Conversion starts when this acquisition interval (three external clock cycles or approximately 1µs in internal clock mode) ends (Figure 4). When the internal acquisition is combined with the internal clock, the aperture jitter can be as high as 200ps. Internal clock users wishing to achieve the 50ps jitter specification should always use external acquisition mode.

External Acquisition

Use external acquisition mode for precise control of the sampling aperture and/or dependent control of acquisition and conversion times. The user controls acquisition and start-of-conversion with two separate write pulses. The first pulse, written with ACQMOD = 1, starts an acquisition interval of indeterminate length. The second write pulse, written with ACQMOD = 0 (all other bits in the control byte are unchanged), terminates acquisition and starts conversion on $\overline{WR}$ rising edge (Figure 5).

The address bits for the input multiplexer must have the same values on the first and second write pulses. Power-down mode bits (PD0, PD1) can assume new values on the second write pulse (see the *Power-Down Modes* section). Changing other bits in the control byte corrupts the conversion.

Reading a Conversion

A standard interrupt signal, $\overline{INT}$, is provided to allow the MAX1090/MAX1092 to flag the µP when the conversion has ended and a valid result is available. $\overline{INT}$ goes low when the conversion is complete and the output data is ready (Figures 4 and 5). $\overline{INT}$ returns high on the first read cycle or if a new control byte is written.

Selecting Clock Mode

The MAX1090/MAX1092 operate with an internal or external clock. Control bits D6 and D7 select either internal or external clock mode. The part retains the last-requested clock mode if a power-down mode is selected in the current input word. For both internal and external clock modes, internal or external acquisition can be used. At power-up, the MAX1090/MAX1092 enter the default external clock mode.

Table 1. Control Byte Functional Description

BIT	NAME	FUNCTION		
D7, D6	PD1, PD0	**PD1** and **PD0** select the various clock and power-down modes.		
		0	**0**	Full Power-Down Mode. Clock mode is unaffected.
		0	**1**	Standby Power-Down Mode. Clock mode is unaffected.
		1	**0**	Normal Operation Mode. Internal clock mode is selected.
		1	**1**	Normal Operation Mode. External clock mode is selected.
D5	ACQMOD	ACQMOD = 0: Internal Acquisition Mode ACQMOD = 1: External Acquisition Mode		
D4	SGL/$\overline{DIF}$	SGL/$\overline{DIF}$ = 0: Pseudo-Differential Analog Input Mode SGL/$\overline{DIF}$ = 1: Single-Ended Analog Input Mode In single-ended mode, input signals are referred to COM. In pseudo-differential mode, the voltage difference between two channels is measured (Tables 2 and 3).		
D3	UNI/$\overline{BIP}$	UNI/$\overline{BIP}$ = 0: Bipolar Mode UNI/$\overline{BIP}$ = 1: Unipolar Mode In unipolar mode, an analog input signal from 0 to V_{REF} can be converted; in bipolar mode, the signal can range from -V_{REF}/2 to +V_{REF}/2.		
D2, D1, D0	A2, A1, A0	Address bits A2, A1, A0 select which of the 8/4 (MAX1090/MAX1092) channels is to be converted (Tables 3 and 4).		

MAX1090/MAX1092

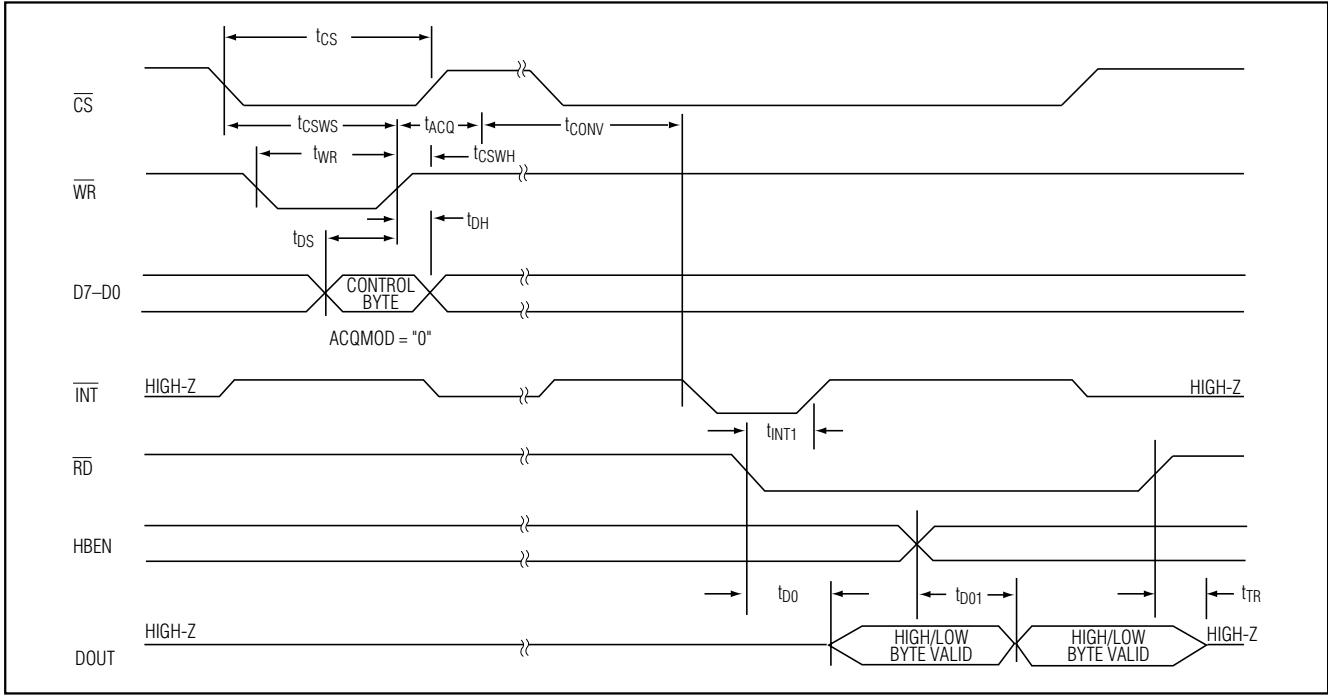

Figure 4. Conversion Timing Using Internal Acquisition Mode
Figure 5. Conversion Timing Using External Acquisition Mode

MAXIM

MAX1090/MAX1092

Internal Clock Mode

Select internal clock mode to release the µP from the burden of running the SAR conversion clock. To select this mode, bit D7 of the control byte must be set to 1 and bit D6 must be set to 0. The internal clock frequency is then selected, resulting in a 3.6µs conversion time. When using the internal clock mode, connect the CLK pin either high or low to prevent the pin from floating.

External Clock Mode

To select the external clock mode, bits D6 and D7 of the control byte must be set to one. Figure 6 shows the clock and $\overline{WR}$ timing relationship for internal (Figure 6a) and external (Figure 6b) acquisition modes with an external clock. Proper operation requires a 100kHz to 7.6MHz clock frequency with 30% to 70% duty cycle. Operating the MAX1090/MAX1092 with clock frequencies lower than 100kHz is not recommended, because it causes a voltage droop across the hold capacitor in the T/H stage, which results in degraded performance.
Figure 6a. External Clock and $\overline{WR}$ Timing (Internal Acquisition Mode)

Figure 6b. External Clock and $\overline{WR}$ Timing (External Acquisition Mode)

400ksps, +5V, 8-/4-Channel, 10-Bit ADCs with +2.5V Reference and Parallel Interface

Digital Interface

Input (control byte) and output data are multiplexed on a three-state parallel interface. This parallel interface (I/O) can easily be interfaced with standard µPs. The signals $\overline{CS}$, $\overline{WR}$, and $\overline{RD}$ control the write and read operations. $\overline{CS}$ represents the chip-select signal, which enables a µP to address the MAX1090/MAX1092 as an I/O port. When high, $\overline{CS}$ disables the CLK, $\overline{WR}$, and $\overline{RD}$ inputs and forces the interface into a high-impedance (high-Z) state.

Input Format

The control byte is latched into the device on pins D7–D0 during a write command. Table 2 shows the control byte format.

Output Format

The output format for the MAX1090/MAX1092 is binary in unipolar mode and two's complement in bipolar mode. When reading the output data, $\overline{CS}$ and $\overline{RD}$ must be low. When HBEN = 0, the lower 8 bits are read. With HBEN = 1, the upper 2 bits are available and the output data bits D7–D2 are set either low in unipolar mode or to the value of the MSB in bipolar mode (Table 5).

Figure 7. Reference Voltage Adjustment with External Potentiometer

_____Applications Information

Power-On Reset
When power is first applied, internal power-on reset circuitry activates the MAX1090/MAX1092 in external clock mode and sets $\overline{INT}$ high. After the power supplies stabilize, the internal reset time is 10µs, and no conversions should be attempted during this phase. When using the internal reference, 500µs are required for V$_{REF}$ to stabilize.

Internal and External Reference
The MAX1090/MAX1092 can be used with an internal or external reference voltage. An external reference can be connected directly to REF or REFADJ.

An internal buffer is designed to provide +2.5V at REF for both devices. The internally trimmed +1.22V reference is buffered with a +2.05V/V gain.

Internal Reference
The full-scale range with the internal reference is +2.5V with unipolar inputs and ±1.25V with bipolar inputs. The internal reference buffer allows for small adjustments (±100mV) in the reference voltage (Figure 7).

Note: The reference buffer must be compensated with an external capacitor (4.7µF min) connected between REF and GND to reduce reference noise and switching spikes from the ADC. To further minimize reference noise, connect a 0.01µF capacitor between REFADJ and GND.

External Reference
With the MAX1090/MAX1092, an external reference can be placed at either the input (REFADJ) or the output (REF) of the internal reference-buffer amplifier.
Using the REFADJ input makes buffering the external reference unnecessary. The REFADJ input impedance is typically 17kΩ.

When applying an external reference to REF, disable the internal reference buffer by connecting REFADJ to V$_{DD}$. The DC input resistance at REF is 25kΩ. Therefore, an external reference at REF must deliver up to 200µA DC load current during a conversion and have an output impedance less than 10Ω. If the reference has higher output impedance or is noisy, bypass it close to the REF pin with a 4.7µF capacitor.

Power-Down Modes
To save power, place the converter in a low-current shutdown state between conversions. Select standby mode or shutdown mode using bits D6 and D7 of the control byte (Tables 1 and 2). In both software power-down modes, the parallel interface remains active, but the ADC does not convert.

Standby Mode
While in standby mode, the supply current is 1mA (typ). The part powers up on the next rising edge on $\overline{WR}$ and is ready to perform conversions. This quick turn-on time allows the user to realize significantly reduced power consumption for conversion rates below 400ksps.

Shutdown Mode
Shutdown mode turns off all chip functions that draw quiescent current, reducing the typical supply current to 2µA immediately after the current conversion is completed. A rising edge on $\overline{WR}$ causes the MAX1090/MAX1092 to exit shutdown mode and return to normal operation. To achieve full 10-bit accuracy with a 4.7µF reference bypass capacitor, 500µs is required after power-up. Waiting 500µs in standby mode, instead of in full-power mode, can reduce power consumption by a factor of 3 or more. When using an external reference,

400ksps, +5V, 8-/4-Channel, 10-Bit ADCs with +2.5V Reference and Parallel Interface

only 50µs are required after power-up. Enter standby mode by performing a dummy conversion with the control byte specifying standby mode.

Note: Bypass capacitors larger than 4.7µF between REF and GND result in longer power-up delays.

Transfer Function

Table 6 shows the full-scale voltage ranges for unipolar and bipolar modes.

Figure 8 depicts the nominal, unipolar input/output (I/O) transfer function, and Figure 9 shows the bipolar I/O transfer function. Code transitions occur halfway between successive-integer LSB values. Output coding is binary, with 1 LSB = V_{REF} / 1024.

Maximum Sampling Rate/ Achieving 475ksps

When running at the maximum clock frequency of 7.6MHz, the specified 400ksps throughput is achieved by completing a conversion every 19 clock cycles: 1 write cycle, 3 acquisition cycles, 13 conversion cycles, and 2 read cycles. This assumes that the results of the last conversion are read before the next control byte is written. It's possible to achieve higher throughputs (Figure 10), up to 475ksps, by first writing a control word to begin the acquisition cycle of the next conversion, then reading the results of the previous conversion from the bus. This technique allows a conversion to be completed every 16 clock cycles. Note that switching the data bus during acquisition or conversion can cause additional supply noise that can make it difficult to achieve true 10-bit performance.

Layout, Grounding, and Bypassing

For best performance, use printed circuit boards. Wire-wrap configurations are not recommended since the layout should ensure proper separation of analog and digital traces. Do not run analog and digital lines parallel to each other, and do not lay out digital signal paths underneath the ADC package. Use separate analog and digital PC board ground sections with only one star point (Figure 11) connecting the two ground systems (analog and digital). For lowest noise operation, ensure the ground return to the star ground's power supply is low impedance and as short as possible. Route digital signals far away from sensitive analog and reference inputs.

Figure 8. Unipolar Transfer Function

MAXIM

400ksps, +5V, 8-/4-Channel, 10-Bit ADCs with +2.5V Reference and Parallel Interface

High-frequency noise in the power supply (V_{DD}) could influence the proper operation of the ADC's fast comparator. Bypass V_{DD} to the star ground with a network of two parallel capacitors, 0.1µF and 4.7µF, located as close as possible to the MAX1090/MAX1092 power-supply pin. Minimize capacitor lead length for best supply-noise rejection, and add an attenuation resistor (5Ω) if the power supply is extremely noisy.

Definitions

Integral Nonlinearity

Integral nonlinearity (INL) is the deviation of the values on an actual transfer function from a straight line. This straight line can be either a best-straight-line fit or a line drawn between the end points of the transfer function, once offset and gain errors have been nullified. The MAX1090/MAX1092's INL is measured using the end-point method.

Differential Nonlinearity

Differential nonlinearity (DNL) is the difference between an actual step width and the ideal value of 1 LSB. A DNL error specification of less than 1 LSB guarantees no missing codes and a monotonic transfer function.

Aperture Jitter

Aperture jitter (t_{AJ}) is the sample-to-sample variation in the time between the samples.

Aperture Delay

Aperture delay (t_{AD}) is the time between the rising edge of the sampling clock and the instant when an actual sample is taken.

MAX1090/MAX1092

Figure 11. Power-Supply and Grounding Connections

Signal-to-Noise Ratio

For a waveform perfectly reconstructed from digital samples, signal-to-noise ratio (SNR) is the ratio of the full-scale analog input (RMS value) to the RMS quantization error (residual error). The ideal theoretical minimum analog-to-digital noise is caused by quantization error only and results directly from the ADC's resolution (N bits):

$$SNR = (6.02 \times N + 1.76)dB$$

In reality, there are other noise sources besides quantization noise, including thermal noise, reference noise, clock jitter, etc. Therefore, SNR is computed by taking the ratio of the RMS signal to the RMS noise, which includes all spectral components minus the fundamental, the first five harmonics, and the DC offset.

Signal-to-Noise Plus Distortion

Signal-to-noise plus distortion (SINAD) is the ratio of the fundamental input frequency's RMS amplitude to the RMS equivalent of all other ADC output signals.

$$SINAD (dB) = 20 \times log (Signal_{RMS} / Noise_{RMS})$$

Effective Number of Bits

Effective number of bits (ENOB) indicates the global accuracy of an ADC at a specific input frequency and sampling rate. An ideal ADC's error consists of quantization noise only. With an input range equal to the ADC's full-scale range, calculate the ENOB as follows:

$$ENOB = (SINAD - 1.76) / 6.02$$

Total Harmonic Distortion

Total harmonic distortion (THD) is the ratio of the RMS sum of the input signal's first five harmonics to the fundamental itself. This is expressed as:

$$THD = 20 \times log \left(\sqrt{\left(V_2{}^2 + V_3{}^2 + V_4{}^2 + V_5{}^2 \right)} / V_1 \right)$$

where V_1 is the fundamental amplitude, and V_2 through V_5 are the amplitudes of the 2nd- through 5th-order harmonics.

Spurious-Free Dynamic Range

Spurious-free dynamic range (SFDR) is the ratio of the RMS amplitude of the fundamental (maximum signal component) to the RMS value of the next-largest distortion component.
